Roger Koenker (CEMMAP & UIUC) Censored Quantile Regression and Survival M

Quantile Regression for Duration (Survival) Models

A wide variety of survival analysis models, following Doksum and Gasko (1990), may be written as,

$$h(\mathsf{T}_{\mathsf{i}}) = \mathsf{x}_{\mathsf{i}}^{\top}\beta + \mathfrak{u}_{\mathsf{i}}$$

where h is a monotone transformation, and

- T<sub>i</sub> is an observed survival time,
- x<sub>i</sub> is a vector of covariates,
- β is an unknown parameter vector
- $\{u_i\}$  are iid with df F.

## The Cox Model

For the proportional hazard model with

$$\log \lambda(t|x) = \log \lambda_0(t) - x^\top \beta$$

the conditional survival function in terms of the integrated baseline hazard  $\Lambda_0(t)=\int_0^t\lambda_0(s)ds$  as,

$$\log(-\log(S(t|x))) = \log \Lambda_0(t) - x^\top \beta$$

so, evaluating at  $t = T_i$ , we have the model,

$$\log \Lambda_0(\mathsf{T}) = \mathsf{x}^\top \beta + \mathfrak{u}$$

for  $u_i$  iid with df  $F_0(u) = 1 - e^{-e^u}$ .

## The Bennett (Proportional-Odds) Model

For the proportional odds model, where the conditional odds of death  $\Gamma(t|x)=F(t|x)/(1-F(t|x))$  are written as,

 $\log \Gamma(t|x) = \log \Gamma_0(t) - x^\top \beta,$ 

we have, similarly,

$$\log \Gamma_0(\mathsf{T}) = \mathsf{x}^\top \beta + \mathfrak{u}$$

for u iid logistic with  $F_0(u) = (1 + e^{-u})^{-1}$ .

#### Accelerated Failure Time Model

In the accelerated failure time model we have

 $\log(T_i) = x_i^\top \beta + u_i$ 

SO

$$P(T > t) = P(e^{u} > te^{-x\beta})$$
$$= 1 - F_0(te^{-x\beta})$$

where  $F_0(\cdot)$  denotes the df of  $e^u$ , and thus,

$$\lambda(\mathbf{t}|\mathbf{x}) = \lambda_0(\mathbf{t}e^{-\mathbf{x}\beta})e^{-\mathbf{x}\beta}$$

where  $\lambda_0(\cdot)$  denotes the hazard function corresponding to  $F_0$ . In effect, the covariates act to rescale time in the baseline hazard.

### Beyond the Transformation Model

The common feature of all these models is that after transformation of the observed survival times we have:

- a pure location-shift, iid-error regression model
- $\bullet$  covariate effects shift the center of the distribution of h(T), but
- covariates cannot affect scale, or shape of this distribution

# An Application: Longevity of Mediterrean Fruit Flies

In the early 1990's there were a series of experiments designed to study the survival distribution of lower animals. One of the most influential of these was:

CAREY, J.R., LIEDO, P., OROZCO, D. AND VAUPEL, J.W. (1992) Slowing of mortality rates at older ages in large Medfly cohorts, Science, 258, 457-61.

- 1,203,646 medflies survival times recorded in days
- Sex was recorded on day of death
- Pupae were initially sorted into one of five size classes
- 167 aluminum mesh cages containing roughly 7200 flies
- Adults were given a diet of sugar and water ad libitum

## Major Conclusions of the Medfly Experiment

- Mortality rates declined at the oldest observed ages. contradicting the traditional view that aging is an inevitable, monotone process of senescence.
- The right tail of the survival distribution was, at least by human standards, remarkably long.
- There was strong evidence for a crossover in gender specific mortality rates.

#### Lifetable Hazard Estimates by Gender

Smoothed mortality rates for males and females.

## Quantile Regression Model (Geling and K (JASA,2001))

Criticism of the Carey et al paper revolved around whether declining hazard rates were a result of confounding factors of cage density and initial pupal size. Our basic QR model included the following covariates:

$$\begin{split} Q_{\text{log}(\mathsf{T}_{i})}(\tau|x_{i}) &= \beta_{0}(\tau) + \beta_{1}(\tau)\text{SEX} + \beta_{2}(\tau)\text{SIZE} \\ &+ \beta_{3}(\tau)\text{DENSITY} + \beta_{4}(\tau)\%\text{MALE} \end{split}$$

- SEX Gender
- SIZE Pupal Size in mm
- DENSITY Initial Density of Cage
- %MALE Initial Proportion of Males

There are currently 3 approaches to handling censored survival data within the quantile regression framework:

- Powell (1986) Fixed Censoring
- Portnoy (2003) Random Censoring, Kaplan-Meier Analogue
- Peng/Huang (2008) Random Censoring, Nelson-Aalen Analogue Available for R in the package quantreg.

#### Powell's Approach for Fixed Censoring

Rationale Quantiles are equivariant to monotone transformation:

$$Q_{h(Y)}(\tau) = h(Q_Y(\tau))$$
 for  $h \nearrow$ 

Model  $Y_i = T_i \wedge C_i \equiv \min\{T_i, C_i\}$ 

$$Q_{\mathbf{Y}_{i}|\mathbf{x}_{i}}(\tau|\mathbf{x}_{i}) = \mathbf{x}_{i}^{\top}\boldsymbol{\beta}(\tau) \wedge C_{i}$$

Data Censoring times are known for all observations

$$\{Y_i, C_i, x_i : i = 1, \cdots, n\}$$

Estimator Conditional quantile functions are nonlinear in parameters:

$$\hat{\boldsymbol{\beta}}(\tau) = \textit{argmin} \sum \rho_{\tau}(\boldsymbol{Y}_i - \boldsymbol{x}_i^\top \boldsymbol{\beta} \wedge \boldsymbol{C}_i)$$

## Portnoy's Approach for Random Censoring I

Rationale Efron's (1967) interpretation of Kaplan-Meier as shifting mass of censored observations to the right:

Algorithm Until we "encounter" a censored observation KM quantiles can be computed by solving, starting at  $\tau = 0$ ,

$$\hat{\xi}(\tau) = \textit{argmin}_{\xi} \sum_{i=1}^n \rho_{\tau}(Y_i - \xi)$$

Once we "encounter" a censored observation, i.e. when  $\hat{\xi}(\tau_i) = y_i$  for some  $y_i$  with  $\delta_i = 0$ , we split  $y_i$  into two parts:  $\mathbf{y}_i^{(1)} = y_i$  with weight  $w_i = (\tau - \tau_i)/(1 - \tau_i)$   $\mathbf{y}_i^{(2)} = y_\infty = \infty$  with weight  $1 - w_i$ . Then denoting the index set of concored observations

Then denoting the index set of censored observations "encountered" up to  $\tau$  by  $K(\tau)$  we can solve

$$\label{eq:min_states} \text{min} \sum_{i \not\in K(\tau)} \rho_\tau(Y_i - \xi) + \sum_{i \in K(\tau)} [w_i(\tau) \rho_\tau(Y_i - \xi) + (1 - w_i(\tau)) \rho_\tau(y_\infty - \xi)].$$

・ 「 ・ ・ ・ ・ ・ ・ ・

#### Portnoy's Approach for Random Censoring II

When we have covariates we can replace  $\xi$  by the inner product  $x_i^\top\beta$  and solve:

$$\min \sum_{i \notin K(\tau)} \rho_{\tau}(Y_i - x_i^{\top}\beta) + \sum_{i \in K(\tau)} [w_i(\tau)\rho_{\tau}(Y_i - x_i^{\top}\beta) + (1 - w_i(\tau))\rho_{\tau}(y_{\infty} - x_i^{\top}\beta)].$$

At each  $\tau$  this is a simple, weighted linear quantile regression problem.

### Portnoy's Approach for Random Censoring II

When we have covariates we can replace  $\xi$  by the inner product  $x_i^\top \beta$  and solve:

$$\min \sum_{i \notin K(\tau)} \rho_{\tau}(Y_i - x_i^{\top}\beta) + \sum_{i \in K(\tau)} [w_i(\tau)\rho_{\tau}(Y_i - x_i^{\top}\beta) + (1 - w_i(\tau))\rho_{\tau}(y_{\infty} - x_i^{\top}\beta)].$$

At each  $\tau$  this is a simple, weighted linear quantile regression problem. The following R code fragment replicates an analysis in Portnoy (2003):

```
require(quantreg)
data(uis)
fit <- crq(Surv(log(TIME), CENSOR) ~ ND1 + ND2 + IV3 +
        TREAT + FRAC + RACE + AGE * SITE, data = uis, method = "Por")
Sfit <- summary(fit,1:19/20)
PHit <- coxph(Surv(TIME, CENSOR) ~ ND1 + ND2 + IV3 +
        TREAT + FRAC + RACE + AGE * SITE, data = uis)
plot(Sfit, CoxPHit = PHit)</pre>
```

#### Reanalysis of the Hosmer-Lemeshow Drug Relapse Data

Roger Koenker (CEMMAP & UIUC) Censored Quantile Regression and Survival M

LSE: 17.5.2010 18 / 28

### Peng and Huang's Approach for Random Censoring I

Rationale Extend the martingale representation of the Nelson-Aalen estimator of the cumulative hazard function to produce an "estimating equation" for conditional quantiles. Model AFT form of the quantile regression model:

 $\textit{Prob}(\log T_i \leqslant x_i^\top \beta(\tau)) = \tau$ 

 $\begin{array}{l} \mbox{Data } \{(Y_i, \delta_i): i = 1, \cdots, n\} \ Y_i = T_i \land C_i, \ \delta_i = I(T_i < C_i) \\ \mbox{Martingale } \ \mbox{We have } EM_i(t) = 0 \ \mbox{for } t \geqslant 0, \ \mbox{where:} \end{array}$ 

$$\begin{array}{lll} M_i(t) &=& N_i(t) - \Lambda_i(t \wedge Y_i | x_i) \\ N_i(t) &=& I(\{Y_i \leqslant t\}, \{\delta_i = 1\}) \\ \Lambda_i(t) &=& -\log(1 - F_i(t | x_i)) \\ F_i(t) &=& \textit{Prob}(T_i \leqslant t | x_i) \end{array}$$

Peng and Huang's Approach for Random Censoring II

The estimating equation becomes,

$$\mathsf{En}^{-1/2}\sum x_i[\mathsf{N}_i(\mathsf{exp}(x_i^\top\beta(\tau))) - \int_0^\tau \mathrm{I}(Y_i \geqslant \mathsf{exp}(x_i^\top\beta(u)))d\mathsf{H}(u) = 0.$$

where  $H(\mathfrak{u})=-\log(1-\mathfrak{u})$  for  $\mathfrak{u}\in[0,1),$  after rewriting:

$$\begin{split} \Lambda_i(\text{exp}(x_i^\top\beta(\tau))\wedge Y_i|x_i)) &= & H(\tau)\wedge H(F_i(Y_i|x_i)) \\ &= & \int_0^\tau I(Y_i \geqslant \text{exp}(x_i^\top\beta(u)))dH(u), \end{split}$$

Approximating the integral on a grid,  $0 = \tau_0 < \tau_1 < \cdots < \tau_J < 1$  yields a simple linear programming formulation to be solved at the gridpoints.

## Alice in Asymptopia

It might be thought that the Powell estimator would be more efficient than the Portnoy and Peng-Huang estimators given that it imposes more stringent data requirements. Comparing asymptotic behavior and finite sample performance in the simplest one-sample setting indicates otherwise.

	median	Kaplan-Meier	Nelson-Aalen	Powell	Leurgans Ĝ	Leurgans G
n= 50	1.602	1.972	2.040	2.037	2.234	2.945
n= 200	1.581	1.924	1.930	2.110	2.136	2.507
n= 500	1.666	2.016	2.023	2.187	2.215	2.742
n= 1000	1.556	1.813	1.816	2.001	2.018	2.569
$n = \infty$	1.571	1.839	1.839	2.017	2.017	2.463

Scaled MSE for Several Estimators of the Median: Mean squared error estimates are scaled by sample size to conform to asymptotic variance computations. Here,  $T_i$  is standard lognormal, and  $C_i$  is exponential with rate parameter .25, so the proportion of censored observations is roughly 30 percent. 1000 replications.

• Simulation evidence confirms the asymptotic conclusion that the Portnoy and Peng-Huang estimators are quite similar.

- Simulation evidence confirms the asymptotic conclusion that the Portnoy and Peng-Huang estimators are quite similar.
- The martingale representation of the Peng-Huang estimator yields a more complete asymptotic theory than is currently available for the Portnoy estimator.

- Simulation evidence confirms the asymptotic conclusion that the Portnoy and Peng-Huang estimators are quite similar.
- The martingale representation of the Peng-Huang estimator yields a more complete asymptotic theory than is currently available for the Portnoy estimator.
- The Powell estimator, although conceptually attractive, suffers from some serious computational difficulties, imposes strong data requirements, and has an inherent asymptotic efficiency disadvantage.

- Simulation evidence confirms the asymptotic conclusion that the Portnoy and Peng-Huang estimators are quite similar.
- The martingale representation of the Peng-Huang estimator yields a more complete asymptotic theory than is currently available for the Portnoy estimator.
- The Powell estimator, although conceptually attractive, suffers from some serious computational difficulties, imposes strong data requirements, and has an inherent asymptotic efficiency disadvantage.
- Quantile regression provides a flexible complement to classical survival analysis methods, and is now well equipped to handle censoring.
